Training Neural Networks: Forward and Backward Propagation

Multivariate Chain Rule Backpropagation Optimisation Vanishing Gradients Activation Function

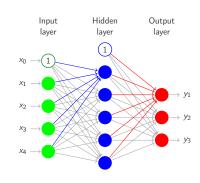

Neural Networks

Output of a neural network can be visualised graphically as *forward* propagation of information.

Neural Networks

- Input layer neurons will be indexed by i.
- ► Hidden layer neurons will be indexed by i.
- Next hidden layer or output layer neurons will be indexed by k.
- ► Weights of *j*-th hidden neuron will be denoted by the vector $\mathbf{w}_{i}^{(1)} \in \mathbb{R}^{D}$.
- ► Weight between *i*-th input neuron and j-th hidden neuron is $w_{ii}^{(1)}$.
- ► Weights of *k*-th output neuron will be denoted by the vector $\mathbf{w}_{\nu}^{(2)} \in \mathbb{R}^{M}$.
- ► Weight between *j*-th hidden neuron and k-th output neuron is $w_{ki}^{(2)}$.

- For input x, denote output of hidden layer as the vector $\mathbf{z}(\mathbf{x}) \in \mathbb{R}^{M}$. ▶ Model $z_i(\mathbf{x})$ as a non-linear function $h(a_i)$
- where pre-activation $a_i = \mathbf{w}_i^{(1)T} \mathbf{x}$ with adjustable parameters $\mathbf{w}_{i}^{(1)}$.
- Hidden Output Input layer layer

So the k-th output can be written as

$$y_k(\mathbf{x}) = f(a_k) = f(\mathbf{w}_k^{(2)T} \mathbf{z}(\mathbf{x}))$$

$$= f\left(\sum_{j=1}^M w_{kj}^{(2)} z_j(\mathbf{x}) + w_{k0}^{(2)}\right) = f\left(\sum_{j=1}^M w_{kj}^{(2)} h\left(\sum_{i=0}^D w_{ji}^{(1)} x_i\right) + w_{k0}^{(2)}\right)$$

where we have prepended $x_0 = 1$ to to absorb bias input and $w_{i0}^{(1)}$ and $w_{\nu_0}^{(2)}$ represent biases.

The computation

$$y_k(\mathbf{x}, \mathbf{W}) = f\left(\sum_{j=1}^{M} w_{kj}^{(2)} h\left(\sum_{i=0}^{D} w_{ji}^{(1)} x_i\right) + w_{k0}^{(2)}\right)$$

can be viewed in two stages:

- **1.** $z_j = h(\mathbf{w}_i^{(1)T}\mathbf{x})$ for j = 1, ..., M.
- **2.** $v_{\nu} = f(\mathbf{w}_{\nu}^{(2)T}\mathbf{z}).$

Neural Networks Forward Propagation

If we define the matrices

$$\mathbf{W}^{(1)} = \underbrace{\begin{bmatrix} \leftarrow \mathbf{w}_{1}^{(1)T} \rightarrow \\ \leftarrow \mathbf{w}_{2}^{(1)T} \rightarrow \\ \vdots \\ \leftarrow \mathbf{w}_{M}^{(1)T} \rightarrow \end{bmatrix}}_{M \times (D+1)} \text{ and } \mathbf{W}^{(2)} = \underbrace{\begin{bmatrix} \leftarrow \mathbf{w}_{1}^{(2)T} \rightarrow \\ \leftarrow \mathbf{w}_{2}^{(2)T} \rightarrow \\ \vdots \\ \leftarrow \mathbf{w}_{K}^{(2)T} \rightarrow \end{bmatrix}}_{K \times (M+1)}$$

then forward propagation constitutes

- 1. $z = h(W^{(1)}x)$.
- 2. Prepend 1 to z.
- 3. $y = f(W^{(2)}z)$.

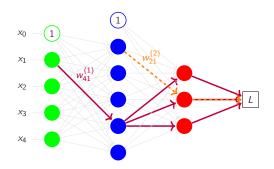

Gradients

- Regression requires continuous output $y_k \in \mathbb{R}$.
- So use *identity* activation function $y_k = f(a_k) = a_k$.
- Loss can be written as

$$L(\mathbf{W}^{(1)}, \mathbf{W}^{(2)}) = \frac{1}{2} \sum_{n=1}^{N} \underbrace{\|\mathbf{y}_n - \mathbf{t}_n\|^2}_{L_n} = \frac{1}{2} \sum_{n=1}^{N} \sum_{k=1}^{K} (y_{nk} - t_{nk})^2$$

- Loss L depends on sum of individual losses L_n.
- In the following, we will focus on loss L_n for the *n*-th training sample.
- \triangleright We will drop n for notational clarity and refer to L_n simply as L.

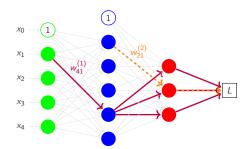

How do weights influence loss?

- \triangleright $w_{ki}^{(2)}$ influences $a_k^{(2)}$ which influences y_k which influences L.
- For scalar dependencies, use chain rule.
- $w_{ii}^{(1)}$ influences $a_i^{(1)}$ which influences z_i which influences $a_1^{(2)}, a_2^{(2)}, a_3^{(2)}$ which influence y_1, y_2, y_3 which influence L.
- For vector/multivariate dependencies, use multivariate chain rule.

Multivariate Chain Rule Backpropagation Optimisation Vanishing Gradients Activation Fund

How do weights influence loss?

► Layer 2: $L \leftarrow y_k \leftarrow a_k^{(2)} \leftarrow w_{ki}^{(2)}$.

$$L(y_k(a_k^{(2)}(w_{kj}^{(2)})))$$

▶ Layer 1: $L \leftarrow \mathbf{y} \leftarrow \mathbf{a}^{(2)} \leftarrow z_j \leftarrow a_i^{(1)} \leftarrow w_{ii}^{(1)}$.

$$L(\underbrace{y_1(a_1^{(2)}(z_j(a_j^{(1)}(w_{ji}^{(1)}))))}_{y_1(w_{ji}^{(1)})},\underbrace{y_2(a_2^{(2)}(z_j(a_j^{(1)}(w_{ji}^{(1)}))))}_{y_2(w_{ji}^{(1)})},\ldots,\underbrace{y_k(a_k^{(2)}(z_j(a_j^{(1)}(w_{ji}^{(1)})))))}_{y_k(w_{ji}^{(1)})}$$

Multivariate Chain Rule

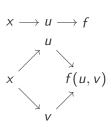

► The chain rule of differentiation states

$$\frac{df(u(x))}{dx} = \frac{df}{du}\frac{du}{dx}$$

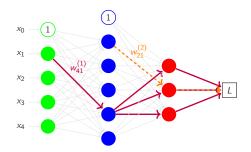

► The *multivariate* chain rule of differentiation states

$$\frac{df(u(x),v(x))}{dx} = \frac{\partial f}{\partial u}\frac{du}{dx} + \frac{\partial f}{\partial v}\frac{dv}{dx}$$

The multivariate chain rule applied to compute derivatives w.r.t weights of hidden layers has a special name – backpropagation.

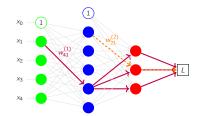

Backpropagation

For the output layer weights

$$\frac{\partial L(y_k(a_k^{(2)}(w_{kj}^{(2)})))}{\partial w_{kj}^{(2)}} = \frac{\partial L}{\partial a_k^{(2)}} \frac{\partial a_k^{(2)}}{\partial w_{kj}^{(2)}} = \delta_k z_j$$

Backpropagation

For the hidden layer weights, using the multivariate chain rule

$$\frac{\partial}{\partial w_{ji}^{(1)}} L(y_{1}(a_{1}^{(2)}(z_{j}(a_{j}^{(1)}(w_{ji}^{(1)})))), y_{2}(a_{2}^{(2)}(z_{j}(a_{j}^{(1)}(w_{ji}^{(1)})))), \dots, y_{k}(a_{k}^{(2)}(z_{j}(a_{j}^{(1)}(w_{ji}^{(1)})))))$$

$$= \frac{\partial L}{\partial a_{j}^{(1)}} \frac{\partial a_{j}^{(1)}}{\partial w_{ji}^{(1)}} = \sum_{k=1}^{K} \underbrace{\frac{\partial L}{\partial a_{k}^{(2)}}}_{\delta_{k}} \underbrace{\frac{\partial a_{j}^{(2)}}{\partial z_{j}}}_{w_{kj}^{(2)}} \underbrace{\frac{\partial a_{j}^{(1)}}{\partial w_{ji}^{(1)}}}_{h'(a_{j}^{(1)})} \underbrace{\frac{\partial a_{j}^{(1)}}{\partial w_{ji}^{(1)}}}_{x_{i}} = \delta_{j}x_{i}$$

Notice that gradient $-\delta \times input$

Backpropagation

▶ It is important to note that

$$\delta_j = h'(a_j) \sum_{k=1}^K \delta_k w_{kj}$$

yields the error δ_j at hidden neuron j by backpropagating the errors δ_k from all output neurons that use the output of neuron j.

- More generally, compute error δ_j at a layer by backpropagating the errors δ_k from next layer.
- ► Hence the names *error backpropagation*, *backpropagation*, or simply *backprop*.
- Very useful machine learning technique that is not limited to neural networks.

$$\delta_j^{(1)} = h'(a_j) \sum_{k=1}^K \delta_k^{(2)} w_{kj}$$

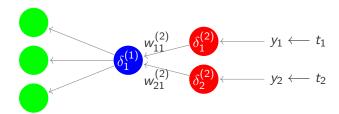

Figure: Visual representation of backpropagation of delta values of layer l+1 to compute delta values of layer 1.

Learning Algorithm

- 1. Forward propagate the input vector \mathbf{x}_n to compute and store activations and outputs of every neuron in every layer.
- 2. Evaluate $\delta_k = \frac{\partial L_n}{\partial a_k}$ for every neuron in output layer.
- 3. Evaluate $\delta_j = \frac{\partial L_n}{\partial a_j}$ for every neuron in *every* hidden layer via backpropagation.

$$\delta_j = h'(a_j) \sum_{k=1}^K \delta_k w_{kj}$$

- **4.** Compute derivative of each weight $\frac{\partial L_n}{\partial w}$ via $\delta \times$ input.
- **5.** Update each weight via gradient descent $w^{\tau+1} = w^{\tau} \eta \frac{\partial L_n}{\partial w}$.

A(-1,1) sigmoidal function

- \triangleright Since range of logistic sigmoid $\sigma(a)$ is (0,1), we can obtain a function with (-1,1) range as $2\sigma(a)-1$.
- \triangleright Another related function with (-1,1) range is the tanh function.

$$tanh(a) = 2\sigma(2a) - 1 = \frac{e^a - e^{-a}}{e^a + e^{-a}}$$

where σ is applied on 2a.

- ▶ Preferred¹over logistic sigmoid as activation function h(a) of hidden neurons.
- ▶ Just like the logistic sigmoid, derivative of tanh(a) is simple: $1 - \tanh^2(a)$. (Prove it.)

¹LeCun et al., 'Efficient backprop'.

 $\delta_j = (1 - z_j^2) \sum_{k=1}^{K} w_{kj}^{(2)} \delta_k$

- ▶ Two-layer MLP for multivariate regression from $\mathbb{R}^D \longrightarrow \mathbb{R}^K$.
- Linear outputs $y_k = a_k$ with half-SSE $L = \frac{1}{2} \sum_{k=1}^{K} (y_k t_k)^2$.
- ightharpoonup M hidden neurons with $tanh(\cdot)$ activation functions.

Forward propagation

Backpropagation

$$a_{j} = \sum_{i=0}^{D} w_{ji}^{(1)} x_{i}$$
 $z_{j} = \tanh(a_{j})$
 $z_{0} = 1$
 $y_{k} = \sum_{j=0}^{M} w_{kj}^{(2)} z_{j}$

 $\delta_k = v_k - t_k$

► Compute derivatives
$$\frac{\partial L}{\partial w_{ii}^{(1)}} = \delta_j x_i$$
 and $\frac{\partial L}{\partial w_{ki}^{(2)}} = \delta_k z_j$.

Numerical derivatives can be computed via finite central differences

$$\frac{\partial L_n}{\partial w_{ji}} = \frac{L_n(w_{ji} + \epsilon) - L_n(w_{ji} - \epsilon)}{2\epsilon} + O(\epsilon^2)$$

- Analytical derivatives computed via backpropagation must be compared with numerical derivatives for a few examples to verify correctness.
- Any implementation of analytical derivatives (not just backpropagation) must be compared with numerical derivatives.
- Notice that we could have avoided backpropagation and computed all required derivatives numerically.
 - ▶ But cost of numerical differentiation is $O(W^2)$ while that of backpropagation is O(W) where W is the total number of weights (and biases) in the network. (Why?)

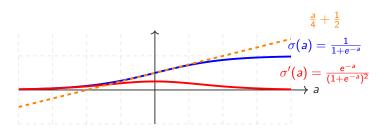

Neural Network training finds local minimum

- ▶ For optimisation, we notice that \mathbf{w}^* must be a stationary point of $E(\mathbf{w})$.
 - Minimum, maximum, or saddle point.
- ► A saddle point is where gradient vanishes but point is not an extremum (Example).
- ► The goal in neural network minimisation is to find a local minimum.
- A global minimum, *even if found*, cannot be verified as globally minimum.
- ▶ Due to symmetry, there are multiple equivalent local minima. Reaching any suitable local minimum is the goal of neural network optimisation.
- Since there are no analytical solutions for w*, we use iterative, numerical procedures.

Optimisation Options

- Options for iterative optimisation
 - Online methods
 - Stochastic gradient descent
 - Stochastic gradient descent using mini-batches
 - Batch methods
 - Batch gradient descent
 - Conjugate gradient descent
 - Quasi-Newton methods
- Online methods
 - converge faster since parameter updates are more frequent, and
 - have greater chance of escaping local minima because stationary point w.r.t to whole data set will generally not be a stationary point w.r.t an individual data point.
- Batch methods: Conjugate gradient descent and quasi-Newton methods
 - are more robust and faster than batch gradient descent, and
 - decrease the error function at each iteration until arriving at a minimum.

Problems with sigmoidal neurons

- ► For large |a|, sigmoid value approaches either 0 or 1. This is called saturation.
- When the sigmoid saturates, the gradient approaches zero.
- Neurons with sigmoidal activations stop learning when they saturate.
- When they are not saturated, they are almost linear.
- There is another reason for the gradient to approach zero during backpropagation.

Vanishing Gradients

- Notice that gradient of the sigmoid is always between 0 and $\frac{1}{4}$.
- Now consider the backpropagation equation.

$$\delta_j = \underbrace{h'(a_j)}_{\leq \frac{1}{4}} \sum_{k=1}^K w_{kj} \delta_k$$

where δ_k will also contain at least one factor of $\leq \frac{1}{4}$.

- \blacktriangleright This means that values of δ_j keep getting smaller as we backpropagate towards the early layers.
- Since gradient = $\delta \times$ input, the gradients also keep getting smaller for the earlier layers. Known as the *vanishing gradients* problem.
- ► Therefore, while the network might be deep, learning will not be deep.

Better Activation Functions

Name	f(a)	Plot	Derivative	Comments
Logistic sigmoid	$\frac{1}{1+e^{-s}}$		f(a)(1-f(a))	Vanishing gradients
Hyperbolic tangent	tanh(a)		$1- \tanh^2(a)$	Vanishing gradients
Rectified Linear Unit (ReLU)	$\begin{cases} a & \text{if } a > 0 \\ 0 & \text{if } a \le 0 \end{cases}$	a	$\begin{cases} 1 \\ 0 \end{cases}$	Dead neurons. Sparsity.
Leaky ReLU	$\begin{cases} a & \text{if } a > 0 \\ ka & \text{if } a \le 0 \end{cases}$	a	$\begin{cases} 1 \\ k \end{cases}$	0 < k < 1
Exponential Linear Unit (ELU)	$\begin{cases} a & \text{if } a > 0 \\ k(e^a - 1) & \text{if } a \le 0 \end{cases}$	a	$\begin{cases} 1 \\ f(a) - k \end{cases}$	<i>k</i> > 0.

- ► Saturated sigmoidal neurons stop learning. Piecewise-linear units keep learning by avoiding saturation.
- ► ELU leads to better accuracy and faster training.
- Take home message: For hidden neurons, use a member of the LU family. They avoid *i*) saturation and *ii*) the vanishing gradient problem.
